Dankel, SJ and Loenneke, JP. Effect sizes for paired data should use the change score variability rather than the pre-test variability. J Strength Cond Res 35(6): 1773–1778, 2021—}

#### What is effect size

- ➤ Variable that provides an overall measure for magnitude of change (Dankel and Loenneke (2021))
- ▶ Differs from a T-statistic because sample size is not included
- ▶ Quantifies how much the mean of the post-treatment differs from the mean of the baseline score in terms of a certain standard deviation.
  - Specifically, they are looking at this comparison from the lens of meta-analyses for exercise science and sports medicine

## Authors' Aims

- ► To convince the audience through analysis that baseline and post-test standard deviations (study sample measures of variability) don't tell the full story on the overall variability of the intervention.
- ➤ To convince the readers that the heterogeneity of the study sample can play a part in unintentionally influencing effect size measurements.

How would one describe the two types of aforementioned variability?

# Variability of the Study Sample

- Any measure of difference between subjects in a given treatment group
- Represented by the Baseline and Post-treatment Standard Deviation.
- ▶ Dankel and Loenneke (2021) and his team claim that the use of this type of variability in paired-sample studies is useless as it has nothing to do with the treatment itself

## Variability of the Intervention

- ► Any measure of difference between baseline and post-treatment measure
- Represented in this case by the Standard Deviation of Change Scores (I will elaborate on this later)
- ▶ Dankel and his team prefer this method of assessing variability

#### Dr. Scott Dankel

- ▶ Professor at Rowan University, a public research university in New Jersey
- ▶ Attended the University of Mississippi to pursue a Masters and PhD in Exercise Science
- Research Interests include acute and chronic adaptations to blood flow restricted exercise (Lab 2024)

## Dr. Jeremy Paul Loenneke

- Professor at The University of Mississippi
- Attended Southeast Missouri State for his Bachelors and Masters in Nutrition and Exercise Science
- Eventually got his PhD in Exercise Physiology at the University of Oklahoma
- Research Discipline is in Skeletal Muscle Plasticity (Ole Miss 2024)
- Regarding the disciplines of the authors, this paper was published in The Journal of Strength and Conditioning Research. This is a good example of the use of statistics as an interdisciplinary tool

#### Introduction

#### Specific Effect Size Measures

The author's claim that the common effect size measures listed below are used exhaustively in meta-analyses in the exercise science discipline.

- ► Cohen's d (Cite)
- ► Hedge's g (Cite)
- ► Glass delta (Cite)
- ► Each use some combination of baseline standard deviation and post-treatment standard deviation.
- Measures of variability of the study sample

## Paired Data vs. Independent Data

## Independent Data

- Data collected through an Independent design
  - Each subject is only measured once
  - Subjects are allocated into a baseline group and a post-treatment group
  - Study sample variability is more important
  - The pooled standard error is the way to assess this variability

#### Paired Data

- Data that is collected through a Paired Sample design
  - Same subject is assessed at both time points.
  - ▶ Since its based on the same subject, this data is not independent
  - In this type of Design, study sample variability is irrelevant
  - Variability of assessed by standard error of the change scores

Since most meta-analysis data is paired, Dankel's analysis focuses on primarily paired-sample designs. Therefore, the authors believe that intervention variability is the best measure for this specific analysis.

#### Methods

#### Preliminary measures

 $\mathit{M}_{\mathit{change}} = \mathsf{Difference}$  between means of Posttreatment group and baseline group in an independent

 $SD_{bsl}=$  Standard Deviation of the baseline group in an independent design  $SD_{post}=$  Standard Deviation of the posttreatment group in an independent design

 $n_{bsl} =$ The sample size of the baseline group

 $n_{post} =$ The sample size of the posttreatment group

$$SD_{ ext{pooled}} = \sqrt{rac{(n_{ ext{bsl}} - 1)SD_{ ext{bsl}}^2 + (n_{ ext{post}} - 1)SD_{ ext{post}}^2}{n_{ ext{bsl}} + n_{ ext{post}} - 2}}$$

## Calculations of Common Effect Size measures

Cohen's 
$$d = \frac{M_{\text{change}}}{SD_{\text{pooled}}}$$

Glass's 
$$\delta = \frac{\textit{M}_{\text{change}}}{\textit{SD}_{\text{bsl}}}$$

Hedge's 
$$g = C * \frac{M_{\text{change}}}{SD_{\text{pooled}}}$$

Where C is a factor depending on n multiplied to account for small sample sizes

We can calculate an Independent t test statistic:

$$T_{\mathsf{indep}} = rac{\mathit{M}_{\mathsf{change}}}{\sqrt{\mathit{SD}_{\mathsf{pooled}}(rac{1}{\mathit{n}_{\mathsf{bsl}}} + rac{1}{\mathit{n}_{\mathsf{post}}})}}$$

Where d represents Cohen's d. From this it is apparent how using the incorrect effect size can be detrimental to a given analysis when using a Paired Design.

## Analysis and Procedure

#### Figure 1

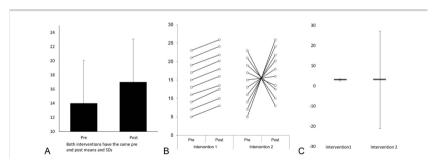

- Describes a dataset with two interventions which have equivalent pre and post scores
- ▶ One intervention has a pre-post correlation of 0.99 and the other one has a pre-post correlation of -0.99.
- ▶ Seek to prove that pre and post scores dont tell the full story on intervention variability

#### Figure 2

- Describes a dataset with two interventions such that one intervention has a higher pre and post standard deviation than intervention 2
- ► They are both correlated the same way
- ▶ Seek to prove that heterogeneity of groups can have a profound effect on Common effect size measures but not on the measure that they define as the "appropriate" effect size

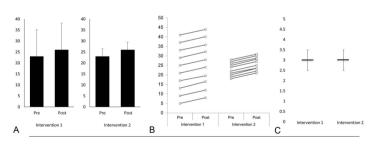

## Figure 1

Graph A shows that both interventions have the same pre and post means and standard deviations. Graph B shows the graph between pre and post, outlining opposite correlations, and Graph C is a representation of the standard error for each of the intervention groups, showing high variability for intervention 2 and low variability for intervention 1. Supports Aim 1.

## Figure 2

Graph A shows that each intervention has the same pre and post mean but different pre-post standard deviations. Graph B shows the graph between pre and post, outlining the same correlations but different pre/post variabilities, and Graph 3 illustrates the variability further by showing that the intervention variability is the same. Supports Aim 2.

# Results (Dankel et. al)

	Pre	Post	ŗ	Change Score	Cohen's d	Glass delta	Hedges g	T statistic	P-value	Appropriate effect size
Intervention 1	14 (SD: 6.05)	17.0 (SD: 6.03)	0.99	3.0 (SD: 0.2582)	0.496	0.497	0.475	36.74	<0.001	11.618
Intervention 2	14 (SD: 6.05)	17.0 (SD: 6.03)	-0.99	3.0 (SD: 12.084)	0.496	0.497	0.475	0.785	0.453	0.248

	Pre	Post	r	Change Score	Cohen's d	Glass delta	Hedges g	T statistic	P-value	Appropriate effect size
Intervention 1	23 (SD: 12.11)	26 (SD: 12.08)	0.99	3.0 (SD: 0.2582)	0.248	0.248	0.237	36.74	<0.001	11.618
Intervention 2	23 (SD: 3.49)	26 (SD: 3.48)	0.99	3.0 (SD: 0.2582)	0.86	0.862	0.824	36.74	<0.001	11.618

- ► Respective to the figures above
- ► Top attempted to prove aim 1
- Bottom attempted to prove aim 2
- ▶ In both, 11.618 is mentioned as the "Appropriate effect size" even though effect sizes rarely range over 4.
- ▶ Standard Deviation of the change scores is suspiciously low as well

## My Results

Recalculate Cohen's dz and show if it changes the significance at all. mention:  $SD_{\rm change}`=\sqrt{SD_{\rm pre}^2+SD_{\rm post}^2-2rSD_{\rm pre}SD_{\rm post}} \ \ {\rm this} \ \ {\rm is} \ \ {\rm the} \ \ {\rm formula} \ \ {\rm used} \ \ {\rm in} \ \ {\rm the} \ \ {\rm article}$ 

#### Discussion

#### General

Impossible to quantify variability of actual intervention when using pre-post scores Figure 1: Intervention 1 produces positive effect where intervention two does not Common effect size measures are reliant on the heterogeneity of the study population Figure 2 shows identical results in 2 diff groups with the only difference being that intervention 1 used a more heterogeneous population

#### Other Issues/Notes

Notes: normalizing using the preSD only is dependent on the subjects recruited rather than effectiveness

Also used in triangulation when trying to obtain sample size calculations
